(57) ABSTRACT

A method of wireless communication determines whether the timing of a non-serving RAT is known. When the timing is known and it is time to report on the non-serving RAT, the UE clears enough consecutive time slots to verify the identity of the base station in the non-serving RAT. During the cleared time slots the identity of the base station is verified. When the timing is unknown and it is time to report on the non-serving RAT, a UE clears enough consecutive time slots to measure the timing of the non-serving RAT and to verify the identity of a base station in the non-serving RAT. During the cleared time slots, the timing is acquired and the identity of the base station is verified.

INTER-RADIO ACCESS TECHNOLOGY (IRAT) HANDOVER

BACKGROUND

1. Field

Aspects of the present disclosure relate generally to wireless communication systems, and more particularly, to improving IRAT handover performance.

2. Background

Wireless communication networks are widely deployed to provide various communication services such as telephony, video, data, messaging, broadcasts, and so on. Such networks, which are usually multiple access networks, support communications for multiple users by sharing the available 15 network resources. One example of such a network is the Universal Terrestrial Radio Access Network (UTRAN). The UTRAN is the radio access network (RAN) defined as a part of the Universal Mobile Telecommunications System (UMTS), a third generation (3G) mobile phone technology 20 supported by the 3rd Generation Partnership Project (3GPP). The UMTS, which is the successor to Global System for Mobile Communications (GSM) technologies, currently supports various air interface standards, such as Wideband-Code Division Multiple Access (W-CDMA), Time Division-Code 25 Division Multiple Access (TD-CDMA), and Time Division-Synchronous Code Division Multiple Access (TD-SCDMA). For example, China is pursuing TD-SCDMA as the underlying air interface in the UTRAN architecture with its existing GSM infrastructure as the core network. The UMTS also 30 supports enhanced 3G data communications protocols, such as High Speed Packet Access (HSPA), which provides higher data transfer speeds and capacity to associated UMTS networks. HSPA is a collection of two mobile telephony protocols, High Speed Downlink Packet Access (HSDPA) and 35 High Speed Uplink Packet Access (HSUPA), that extends and improves the performance of existing wideband protocols.

As the demand for mobile broadband access continues to increase, research and development continue to advance the UMTS technologies not only to meet the growing demand for 40 mobile broadband access, but to advance and enhance the user experience with mobile communications.

SUMMARY

One aspect discloses a method of wireless communication and includes determining whether the timing of a non-serving RAT is known. When it is determined the timing is unknown and when it is time to report on the non-serving RAT base station, the method includes clearing enough consecutive 50 time slots to measure a timing of the non-serving RAT and to verify an identity of a base station in the non-serving RAT. During the cleared time slots, the timing is acquired and the identity of the base station verified. When it is determined the timing is known and when it is time to report on the non-serving RAT base station, the UE clears enough consecutive time slots to verify an identity of a base station in the non-serving RAT. During the cleared time slots, the identity of the base station is verified.

Another aspect discloses an apparatus for wireless communication and includes means for determining whether the timing of a non-serving RAT is known. When it is determined the timing is unknown and it is time to report on the non-serving RAT base station, the apparatus includes means for clearing enough time slots to measure a timing of the non-serving RAT and to verify an identity of a base station in the non-serving RAT. Also included is means to acquire the tim-

2

ing and means to verify the identity of the base station during the cleared time slots. When it is determined the timing is known and when it is time to report on the non-serving RAT base station, the apparatus includes means for clearing enough consecutive time slots to verify an identity of a base station in the non-serving RAT. Also included is means for verifying the identity of the base station during the cleared time slots.

In another aspect, a computer program product for wireless communications in a wireless network having a non-transitory computer-readable medium is disclosed. The computer readable medium has non-transitory program code recorded thereon which, when executed by the processor(s), causes the processor(s) to perform operations of determining whether the timing of a non-serving RAT is known. When it is determined the timing is unknown and when it is time to report on the non-serving RAT base station, the program code causes the processor(s) to clear enough consecutive time slots to measure a timing of the non-serving RAT and to verify an identity of a base station in the non-serving RAT. The program code causes the processor(s) to acquire the timing and verify the identity of the base station during the cleared time slots. When it is determined the timing is known and when it is time to report on the non-serving RAT base station, the program code causes the processor(s) to clear enough consecutive time slots to verify an identity of a base station in the non-serving RAT. The program code also causes the processor(s) to verify the identity of the base station during the

Another aspect discloses wireless communication having a memory and at least one processor coupled to the memory. The processor(s) is configured to determine whether the timing of a non-serving RAT is known. When it is determined the timing is unknown and when it is time to report on the nonserving RAT base station, the processor(s) clears enough consecutive time slots to measure a timing of the non-serving RAT and to verify an identity of a base station in the nonserving RAT. The processor(s) is also configured to acquire the timing and to verify the identity of the base station during the cleared time slots. When it is determined the timing is known and when it is time to report on the non-serving RAT base station, the processor(s) clears enough consecutive time slots to verify an identity of a base station in the non-serving RAT. The processor(s) is also configured to verify the identity of the base station during the cleared time slots.

This has outlined, rather broadly, the features and technical advantages of the present disclosure in order that the detailed description that follows may be better understood. Additional features and advantages of the disclosure will be described below. It should be appreciated by those skilled in the art that this disclosure may be readily utilized as a basis for modifying or designing other structures for carrying out the same purposes of the present disclosure. It should also be realized by those skilled in the art that such equivalent constructions do not depart from the teachings of the disclosure as set forth in the appended claims. The novel features, which are believed to be characteristic of the disclosure, both as to its organization and method of operation, together with further objects and advantages, will be better understood from the following description when considered in connection with the accompanying figures. It is to be expressly understood, however, that each of the figures is provided for the purpose of illustration and description only and is not intended as a definition of the limits of the present disclosure.

BRIEF DESCRIPTION OF THE DRAWINGS

The features, nature, and advantages of the present disclosure will become more apparent from the detailed description

set forth below when taken in conjunction with the drawings in which like reference characters identify correspondingly throughout.

FIG. 1 is a block diagram conceptually illustrating an example of a telecommunications system.

FIG. 2 is a block diagram conceptually illustrating an example of a frame structure in a telecommunications system.

FIG. 3 is a block diagram conceptually illustrating an example of a node B in communication with a UE in a telecommunications system.

FIG. 4 illustrates network coverage areas according to aspects of the present disclosure.

FIG. **5** is a block diagram illustrating a GSM frame cycle. FIG. **6**A is block diagram illustrating a method for IRAT handover when the timing of a non-serving RAT is not 15 known, according to aspects of the present disclosure.

FIG. **6**B is block diagram illustrating a method for IRAT handover when the timing of a non-serving RAT is known, according to aspects of the present disclosure.

FIG. 7 is a diagram illustrating an example of a hardware 20 implementation for an apparatus employing a processing system according to one aspect of the present disclosure.

DETAILED DESCRIPTION

The detailed description set forth below, in connection with the appended drawings, is intended as a description of various configurations and is not intended to represent the only configurations in which the concepts described herein may be practiced. The detailed description includes specific details 30 for the purpose of providing a thorough understanding of the various concepts. However, it will be apparent to those skilled in the art that these concepts may be practiced without these specific details. In some instances, well-known structures and components are shown in block diagram form in order to 35 avoid obscuring such concepts.

Turning now to FIG. 1, a block diagram is shown illustrating an example of a telecommunications system 100. The various concepts presented throughout this disclosure may be implemented across a broad variety of telecommunication 40 systems, network architectures, and communication standards. By way of example and without limitation, the aspects of the present disclosure illustrated in FIG. 1 are presented with reference to a UMTS system employing a TD-SCDMA standard. In this example, the UMTS system includes a (radio $\,$ 45 access network) RAN 102 (e.g., UTRAN) that provides various wireless services including telephony, video, data, messaging, broadcasts, and/or other services. The RAN 102 may be divided into a number of Radio Network Subsystems (RNSs) such as an RNS 107, each controlled by a Radio 50 Network Controller (RNC) such as an RNC 106. For clarity, only the RNC 106 and the RNS 107 are shown; however, the RAN 102 may include any number of RNCs and RNSs in addition to the RNC 106 and RNS 107. The RNC 106 is an apparatus responsible for, among other things, assigning, 55 reconfiguring and releasing radio resources within the RNS 107. The RNC 106 may be interconnected to other RNCs (not shown) in the RAN 102 through various types of interfaces such as a direct physical connection, a virtual network, or the like, using any suitable transport network.

The geographic region covered by the RNS 107 may be divided into a number of cells, with a radio transceiver apparatus serving each cell. A radio transceiver apparatus is commonly referred to as a node B in UMTS applications, but may also be referred to by those skilled in the art as a base station 65 (BS), a base transceiver station (BTS), a radio base station, a radio transceiver, a transceiver function, a basic service set

4

(BSS), an extended service set (ESS), an access point (AP), or some other suitable terminology. For clarity, two node Bs 108 are shown; however, the RNS 107 may include any number of wireless node Bs. The node Bs 108 provide wireless access points to a core network 104 for any number of mobile apparatuses. Examples of a mobile apparatus include a cellular phone, a smart phone, a session initiation protocol (SIP) phone, a laptop, a notebook, a netbook, a smartbook, a personal digital assistant (PDA), a satellite radio, a global positioning system (GPS) device, a multimedia device, a video device, a digital audio player (e.g., MP3 player), a camera, a game console, or any other similar functioning device. The mobile apparatus is commonly referred to as user equipment (UE) in UMTS applications, but may also be referred to by those skilled in the art as a mobile station (MS), a subscriber station, a mobile unit, a subscriber unit, a wireless unit, a remote unit, a mobile device, a wireless device, a wireless communications device, a remote device, a mobile subscriber station, an access terminal (AT), a mobile terminal, a wireless terminal, a remote terminal, a handset, a terminal, a user agent, a mobile client, a client, or some other suitable terminology. For illustrative purposes, three UEs 110 are shown in communication with the node Bs 108. The downlink (DL), also called the forward link, refers to the communication link from a node B to a UE, and the uplink (UL), also called the reverse link, refers to the communication link from a UE to a node B.

The core network 104, as shown, includes a GSM core network. However, as those skilled in the art will recognize, the various concepts presented throughout this disclosure may be implemented in a RAN, or other suitable access network, to provide UEs with access to types of core networks other than GSM networks.

In this example, the core network 104 supports circuitswitched services with a mobile switching center (MSC) 112 and a gateway MSC (GMSC) 114. One or more RNCs, such as the RNC 106, may be connected to the MSC 112. The MSC 112 is an apparatus that controls call setup, call routing, and UE mobility functions. The MSC 112 also includes a visitor location register (VLR) (not shown) that contains subscriberrelated information for the duration that a UE is in the coverage area of the MSC 112. The GMSC 114 provides a gateway through the MSC 112 for the UE to access a circuit-switched network 116. The GMSC 114 includes a home location register (HLR) (not shown) containing subscriber data, such as the data reflecting the details of the services to which a particular user has subscribed. The HLR is also associated with an authentication center (AuC) that contains subscriber-specific authentication data. When a call is received for a particular UE, the GMSC 114 queries the HLR to determine the UE's location and forwards the call to the particular MSC serving that location.

The core network 104 also supports packet-data services with a serving GPRS support node (SGSN) 118 and a gateway GPRS support node (GGSN) 120. GPRS, which stands for General Packet Radio Service, is designed to provide packet-data services at speeds higher than those available with standard GSM circuit-switched data services. The GGSN 120 provides a connection for the RAN 102 to a packet-based network 122. The packet-based network 122 may be the Internet, a private data network, or some other suitable packet-based network. The primary function of the GGSN 120 is to provide the UEs 110 with packet-based network connectivity. Data packets are transferred between the GGSN 120 and the UEs 110 through the SGSN 118,

which performs primarily the same functions in the packetbased domain as the MSC 112 performs in the circuitswitched domain.

The UMTS air interface is a spread spectrum Direct-Sequence Code Division Multiple Access (DS-CDMA) system. 5 The spread spectrum DS-CDMA spreads user data over a much wider bandwidth through multiplication by a sequence of pseudorandom bits called chips. The TD-SCDMA standard is based on such direct sequence spread spectrum technology and additionally calls for a time division duplexing (TDD), rather than a frequency division duplexing (FDD) as used in many FDD mode UMTS/W-CDMA systems. TDD uses the same carrier frequency for both the uplink (UL) and downlink (DL) between a node B 108 and a UE 110, but divides uplink and downlink transmissions into different time 15 slots in the carrier.

FIG. 2 shows a frame structure 200 for a TD-SCDMA carrier. The TD-SCDMA carrier, as illustrated, has a frame 202 that is 10 ms in length. The chip rate in TD-SCDMA is 1.28 Mcps. The frame 202 has two 5 ms subframes 204, and 20 each of the subframes 204 includes seven time slots, TS0 through TS6. The first time slot, TS0, is usually allocated for downlink communication, while the second time slot, TS1, is usually allocated for uplink communication. The remaining time slots, TS2 through TS6, may be used for either uplink or 25 downlink, which allows for greater flexibility during times of higher data transmission times in either the uplink or downlink directions. A downlink pilot time slot (DwPTS) 206, a guard period (GP) 208, and an uplink pilot time slot (UpPTS) 210 (also known as the uplink pilot channel (UpPCH)) are 30 located between TS0 and TS1. Each time slot, TS0-TS6, may allow data transmission multiplexed on a maximum of 16 code channels. Data transmission on a code channel includes two data portions 212 (each with a length of 352 chips) separated by a midamble 214 (with a length of 144 chips) and 35 followed by a guard period (GP) 216 (with a length of 16 chips). The midamble 214 may be used for features, such as channel estimation, while the guard period 216 may be used to avoid inter-burst interference. Also transmitted in the data portion is some Layer 1 control information, including Syn- 40 chronization Shift (SS) bits 218. Synchronization Shift bits 218 only appear in the second part of the data portion. The Synchronization Shift bits 218 immediately following the midamble can indicate three cases: decrease shift, increase shift, or do nothing in the upload transmit timing. The posi- 45 tions of the SS bits 218 are not generally used during uplink communications.

FIG. 3 is a block diagram of a node B 310 in communication with a UE 350 in a RAN 300, where the RAN 300 may be the RAN 102 in FIG. 1, the node B 310 may be the node B 108in FIG. 1, and the UE 350 may be the UE 110 in FIG. 1. In the downlink communication, a transmit processor 320 may receive data from a data source 312 and control signals from a controller/processor 340. The transmit processor 320 provides various signal processing functions for the data and 55 control signals, as well as reference signals (e.g., pilot signals). For example, the transmit processor 320 may provide cyclic redundancy check (CRC) codes for error detection, coding and interleaving to facilitate forward error correction (FEC), mapping to signal constellations based on various 60 modulation schemes (e.g., binary phase-shift keying (BPSK), quadrature phase-shift keying (QPSK), M-phase-shift keying (M-PSK), M-quadrature amplitude modulation (M-QAM), and the like), spreading with orthogonal variable spreading factors (OVSF), and multiplying with scrambling codes to 65 produce a series of symbols. Channel estimates from a channel processor 344 may be used by a controller/processor 340

6

to determine the coding, modulation, spreading, and/or scrambling schemes for the transmit processor 320. These channel estimates may be derived from a reference signal transmitted by the UE 350 or from feedback contained in the midamble 214 (FIG. 2) from the UE 350. The symbols generated by the transmit processor 320 are provided to a transmit frame processor 330 to create a frame structure. The transmit frame processor 330 creates this frame structure by multiplexing the symbols with a midamble 214 (FIG. 2) from the controller/processor 340, resulting in a series of frames. The frames are then provided to a transmitter 332, which provides various signal conditioning functions including amplifying, filtering, and modulating the frames onto a carrier for downlink transmission over the wireless medium through smart antennas 334. The smart antennas 334 may be implemented with beam steering bidirectional adaptive antenna arrays or other similar beam technologies.

At the UE 350, a receiver 354 receives the downlink transmission through an antenna 352 and processes the transmission to recover the information modulated onto the carrier. The information recovered by the receiver **354** is provided to a receive frame processor 360, which parses each frame, and provides the midamble 214 (FIG. 2) to a channel processor 394 and the data, control, and reference signals to a receive processor 370. The receive processor 370 then performs the inverse of the processing performed by the transmit processor **320** in the node B **310**. More specifically, the receive processor 370 descrambles and despreads the symbols, and then determines the most likely signal constellation points transmitted by the node B 310 based on the modulation scheme. These soft decisions may be based on channel estimates computed by the channel processor 394. The soft decisions are then decoded and deinterleaved to recover the data, control, and reference signals. The CRC codes are then checked to determine whether the frames were successfully decoded. The data carried by the successfully decoded frames will then be provided to a data sink 372, which represents applications running in the UE 350 and/or various user interfaces (e.g., display). Control signals carried by successfully decoded frames will be provided to a controller/processor 390. When frames are unsuccessfully decoded by the receiver processor 370, the controller/processor 390 may also use an acknowledgement (ACK) and/or negative acknowledgement (NACK) protocol to support retransmission requests for those frames.

In the uplink, data from a data source 378 and control signals from the controller/processor 390 are provided to a transmit processor 380. The data source 378 may represent applications running in the UE 350 and various user interfaces (e.g., keyboard). Similar to the functionality described in connection with the downlink transmission by the node B 310, the transmit processor 380 provides various signal processing functions including CRC codes, coding and interleaving to facilitate FEC, mapping to signal constellations, spreading with OVSFs, and scrambling to produce a series of symbols. Channel estimates, derived by the channel processor 394 from a reference signal transmitted by the node B 310 or from feedback contained in the midamble transmitted by the node B 310, may be used to select the appropriate coding, modulation, spreading, and/or scrambling schemes. The symbols produced by the transmit processor 380 will be provided to a transmit frame processor 382 to create a frame structure. The transmit frame processor 382 creates this frame structure by multiplexing the symbols with a midamble 214 (FIG. 2) from the controller/processor 390, resulting in a series of frames. The frames are then provided to a transmitter 356, which provides various signal conditioning functions including amplification, filtering, and modulating the frames

onto a carrier for uplink transmission over the wireless medium through the antenna 352.

The uplink transmission is processed at the node B 310 in a manner similar to that described in connection with the receiver function at the UE 350. A receiver 335 receives the 5 uplink transmission through the antenna 334 and processes the transmission to recover the information modulated onto the carrier. The information recovered by the receiver 335 is provided to a receive frame processor 336, which parses each frame, and provides the midamble 214 (FIG. 2) to the channel processor 344 and the data, control, and reference signals to a receive processor 338. The receive processor 338 performs the inverse of the processing performed by the transmit processor 380 in the UE 350. The data and control signals carried by the successfully decoded frames may then be provided to 15 a data sink 339 and the controller/processor, respectively. If some of the frames were unsuccessfully decoded by the receive processor, the controller/processor 340 may also use an acknowledgement (ACK) and/or negative acknowledgement (NACK) protocol to support retransmission requests for 20

The controller/processors 340 and 390 may be used to direct the operation at the node B 310 and the UE 350, respectively. For example, the controller/processors 340 and 390 may provide various functions including timing, periph- 25 eral interfaces, voltage regulation, power management, and other control functions. In particular, the computer readable media of memory 392 may store data and software for the UE 350. For example, the memory 392 of the UE 350 may store a time slot clearing module 391 which, when executed by the 30 controller/processor 390, configures the UE 350 for clearing enough time slots to perform verification of a base station identity and to acquiring timing when the timing is unknown.

Some networks, such as a newly deployed network, may cover only a portion of a geographical area. Another network, 35 such as an older more established network, may better cover the area, including remaining portions of the geographical area. FIG. 4 illustrates coverage of a newly deployed network, such as a TD-SCDMA network and also coverage of a more established network, such as a GSM network. A geographical 40 area 400 may include GSM cells 402 and TD-SCDMA cells 404. A user equipment (UE) 406 may move from one cell, such as a TD-SCDMA cell 404, to another cell, such as a GSM cell 402. The movement of the UE 406 may specify a handover or a cell reselection.

The handover or cell reselection may be performed when the UE moves from a coverage area of a TD-SCDMA cell to the coverage area of a GSM cell, or vice versa. A handover or cell reselection may also be performed when there is a coverage hole or lack of coverage in the TD-SCDMA network or 50 when there is traffic balancing between the TD-SCDMA and GSM networks. As part of that handover or cell reselection process, while in a connected mode with a first system (e.g., TD-SCDMA) a UE may be specified to perform a measurethe UE may measure the neighbor cells of a second network for signal strength, frequency channel, and base station identity code (BSIC). The UE may then connect to the strongest cell of the second network. Such measurement may be referred to as inter radio access technology (IRAT) measure- 60

The UE may send a serving cell a measurement report indicating results of the IRAT measurement performed by the UE. The serving cell may then trigger a handover of the UE to a new cell in the other RAT based on the measurement report. 65 The triggering may be based on a comparison between measurements of the different RATs. The measurement may

include a TD-SCDMA serving cell signal strength, such as a received signal code power (RSCP) for a pilot channel (e.g., primary common control physical channel (P-CCPCH)). The signal strength is compared to a serving system threshold. The serving system threshold can be indicated to the UE through dedicated radio resource control (RRC) signaling from the network. The measurement may also include a GSM neighbor cell received signal strength indicator (RSSI). The neighbor cell signal strength can be compared with a neighbor system threshold. Before handover or cell reselection, in addition to the measurement processes, the base station IDs (e.g., BSICs) are confirmed and re-confirmed.

During the handover process the UE tunes to the GSM channel to acquire information from the GSM network. Because the available TD-SCDMA continuous time slots are limited (for example, only two or three continuous timeslots are typically available in a radio frame), the UE has limited time to measure the GSM cells and cannot complete a full measurement during a single set of continuous time slots. Thus, a portion of the measurement occurs during the first set of continuous time slots, a further portion of the measurement occurs during the available set of continuous time slots in the next cycle, etc., until enough time was provided to complete the measurement. Consequently, a slower than desired TD-SCDMA to GSM handover occurs.

FIG. 5 is a block diagram illustrating a GSM frame cycle. The GSM frame cycle for the frequency correction channel (FCCH) 502 and synchronization channel (SCH) 504 consists of 51 frames, each of 8 burst periods (BPs). The FCCH 502 is in the first burst period (or BP 0) of frame 0, 10, 20, 30, 40, and the SCH **504** is in the first burst period of frame 1, 11, 21, 31, 41. A single burst period is 15/26 ms and a single frame is 120/26 ms. As shown in FIG. 4, the FCCH period is 10 frames (46.15 ms) or 11 frames (51.77 ms). Also as shown, the SCH period is 10 frames or 11 frames.

IRAT Handover

When a UE camps on a cell and enters connected mode, it measures the power of a neighbor cell (e.g. GSM cell) during idle timeslots to attempt decoding the base station identity code (BSIC) from the neighbor cell's synchronization channel. In one example, the UE camps on a TD-SCDMA cell and then measures the power of a GSM neighbor cell. The frame timeline of the GSM cell is asynchronous with the frame timeline of the TD-SCDMA cell. The UE acquires the timing of the GSM cell through the frequency correction channel (FCCH) and then decodes the synchronization SCH channel on a trial basis. The time to successfully acquire timing information and to decode the base station identity code (BSIC) is randomly distributed and depends on the number of idle timeslots available to perform the IRAT search. If it takes a long time to successfully decode the BSIC, then the opportunity to handover to a neighbor GSM cell may be missed which may then result in call drop.

One aspect of the present disclosure is directed to improvment of a neighboring cell (such as GSM cell). For example, 55 ing the handover performance by clearing some channels in consecutive TD-SCDMA sub-frames to create a gap. The gap may then be used to verify the BSIC and to acquire the timing when it is unknown. In particular, in one aspect, the resulting gap is configured large enough to be utilized for acquiring the neighbor cell timing and to decode BSIC when an Event 3A trigger condition is met. In one example, to provide enough room for transmitting the synchronization channel (SCH) with BSIC information, the created gap is 13 GSM frames. An Event 3A may be triggered when the TD-SCDMA serving cell signal strength is below a first threshold value and the neighbor cell (e.g., GSM cell) signal strength is above a second threshold value. One aspect of the present disclosure

provides for triggering the Event 3A regardless of the number of natural idle timeslots available and the frame alignment condition between a TDS-CDMA serving cell and a neighbor cell.

In one aspect, the UE continues to use natural idle timeslots to measure the neighbor cell signal strength (e.g., a GSM received signal strength indication (RSSI)). The UE also continues to use natural idle time slots to attempt decoding the FCCH for acquiring the timing of the neighbor cell and for attempting to decode the BSIC.

In one aspect, when the timing of the neighbor cell is known (or has already been acquired), the UE may clear enough timeslots to verify the BSIC. In particular, the UE estimates when the BSIC will be transmitted and then clears enough time slots to correspond to the estimates. For 15 example, after an Event 3A trigger condition is met, and the timing of the strongest neighbor cell is acquired, but no BSIC of a neighbor cell has been detected, the timeslot(s) where the SCH hypothesis decodes BSIC is cancelled. In one aspect, two hypotheses may be used to consecutively decode the 20 BSIC with known timing. In one example, the UE may clear about thirteen (13) GSM frames after estimating to make sure the gap is large enough.

Alternately, if the timing of the strongest neighbor cell has not yet been acquired, the UE creates a gap by clearing 25 enough frames to support acquiring the timing and the BSIC decoding. That is, a larger gap is created. In one example, the UE clears about thirteen (13) GSM frames before the time to trigger expires. The UE creates the gap by canceling all channels for a length of time corresponding to the gap being 30 created. Thus, the UE should be able to finish timing acquisition and BSIC decoding during the gap.

In one example, after the UE completes the GSM measurement(s) in the cleared time slots, the UE continues with the BSIC reconfirmation procedure in natural timeslots. The UE 35 can resume communications on the cleared time slots after the identity is verified.

FIG. 6A shows a wireless communication method 601 for IRAT handover when the timing of the non-serving RAT is unknown, according to one aspect of the disclosure. In block 40 610, a UE determines whether the timing of a non-serving radio access technology (RAT) is known. When the timing is unknown and it is time to report on the non-serving base station, the UE, in block 612, clears enough consecutive time slots to measure the timing of the non-serving RAT and to 45 verify the identity of the base station in the non-serving RAT. In block 614, the UE acquires the timing and verifies the identity of the base station during the cleared time slots.

FIG. **6**B shows a wireless communication method **602** for IRAT handover when the timing of the non-serving RAT is 50 known, according to one aspect of the disclosure. In block **620**, a UE determines whether the timing of a non-serving radio access technology (RAT) is known. When the timing is known and it is time to report on the non-serving base station, the UE, in block **622**, clears enough consecutive time slots to 55 verify the identity of the base station in the non-serving RAT. In block **624**, the UE verifies the identity of the base station during the cleared time slots.

In one configuration, an apparatus such as a UE is configured for wireless communication including means for determining. In one aspect, the determining means may be the time slot clearing module 391, controller/processor 390 and/or the memory 392, configured to perform the determining means. The UE is also configured to include means for clearing time slots. In one aspect, the clearing means may be the time slot clearing module 391, the controller/processor 390 and/or the memory 392 configured to perform the clearing means.

10

The UE is also configured to include means for verifying. In one aspect, the verifying means may be the time slot clearing module 391, the controller/processor 390 and/or the memory 392 configured to perform the verifying means. When the timing is unknown, the UE is also configured to include means for acquiring timing. In one aspect, the acquiring means may be the time slot clearing module 391, the antenna 352, receiver 354, receive frame processor 360, receive processor 370, controller/processor 390 and/or the memory 392 configured to perform the acquiring means. In one aspect the means functions recited by the aforementioned means may be a module or any apparatus configured to perform the functions recited by the aforementioned means.

FIG. 7 is a diagram illustrating an example of a hardware implementation for an apparatus 700 employing a processing system 714. The processing system 714 may be implemented with a bus architecture, represented generally by the bus 724. The bus 724 may include any number of interconnecting buses and bridges depending on the specific application of the processing system 714 and the overall design constraints. The bus 724 links together various circuits including one or more processors and/or hardware modules, represented by the processor 722 the modules 702, 704, 706 and the non-transitory computer-readable medium 726. The bus 724 may also link various other circuits such as timing sources, peripherals, voltage regulators, and power management circuits, which are well known in the art, and therefore, will not be described any further.

The apparatus includes a processing system 714 coupled to a transceiver 730. The transceiver 730 is coupled to one or more antennas 720. The transceiver 730 enables communicating with various other apparatus over a transmission medium. The processing system 714 includes a processor 722 coupled to a non-transitory computer-readable medium 726. The processor 722 is responsible for general processing, including the execution of software stored on the computer-readable medium 726. The software, when executed by the processor 722, causes the processing system 714 to perform the various functions described for any particular apparatus. The computer-readable medium 726 may also be used for storing data that is manipulated by the processor 722 when executing software.

The processing system 714 includes a determining module 702 for determining whether the timing of a non-serving RAT is known. The processing system 714 includes a time slot module 704 for clearing enough consecutive time slots to perform identity verification when the timing is known. When the timing is unknown, the time slot module 704 clears enough time slots to acquire timing and to performing identity verification. The processing system also includes a timing and verification module 706 to verify the identity of the base station during the cleared time slots, and when the timing is unknown to also acquire the timing. The modules may be software modules running in the processor 722, resident/ stored in the computer readable medium 726, one or more hardware modules coupled to the processor 722, or some combination thereof. The processing system 714 may be a component of the UE 350 and may include the memory 392, the time slot clearing module 391, and/or the controller/processor 390.

Several aspects of a telecommunications system has been presented with reference to TD-SCDMA and GSM systems. As those skilled in the art will readily appreciate, various aspects described throughout this disclosure may be extended to other telecommunication systems, network architectures and communication standards. By way of example, various

aspects may be extended to other UMTS systems such as W-CDMA, High Speed Downlink Packet Access (HSDPA), High Speed Uplink Packet Access (HSUPA), High Speed Packet Access Plus (HSPA+) and TD-CDMA. Various aspects may also be extended to systems employing Long 5 Term Evolution (LTE) (in FDD, TDD, or both modes), LTE-Advanced (LTE-A) (in FDD, TDD, or both modes), CDMA2000, Evolution-Data Optimized (EV-DO), Ultra Mobile Broadband (UMB), IEEE 802.11 (Wi-Fi), IEEE 802.16 (WiMAX), IEEE 802.20, Ultra-Wideband (UWB), 10 Bluetooth, and/or other suitable systems. The actual telecommunication standard, network architecture, and/or communication standard employed will depend on the specific application and the overall design constraints imposed on the system.

Several processors have been described in connection with various apparatuses and methods. These processors may be implemented using electronic hardware, computer software, or any combination thereof. Whether such processors are implemented as hardware or software will depend upon the 20 particular application and overall design constraints imposed on the system. By way of example, a processor, any portion of a processor, or any combination of processors presented in this disclosure may be implemented with a microprocessor, microcontroller, digital signal processor (DSP), a field-pro- 25 grammable gate array (FPGA), a programmable logic device (PLD), a state machine, gated logic, discrete hardware circuits, and other suitable processing components configured to perform the various functions described throughout this disclosure. The functionality of a processor, any portion of a 30 processor, or any combination of processors presented in this disclosure may be implemented with software being executed by a microprocessor, microcontroller, DSP, or other suitable platform.

Software shall be construed broadly to mean instructions, 35 instruction sets, code, code segments, program code, programs, subprograms, software modules, applications, software applications, software packages, routines, subroutines, objects, executables, threads of execution, procedures, functions, etc., whether referred to as software, firmware, middle-40 ware, microcode, hardware description language, or otherwise. The software may reside on a non-transitory computerreadable medium. A computer-readable medium may include, by way of example, memory such as a magnetic storage device (e.g., hard disk, floppy disk, magnetic strip), an 45 optical disk (e.g., compact disc (CD), digital versatile disc (DVD)), a smart card, a flash memory device (e.g., card, stick, key drive), random access memory (RAM), read only memory (ROM), programmable ROM (PROM), erasable PROM (EPROM), electrically erasable PROM (EEPROM), a 50 register, or a removable disk. Although memory is shown separate from the processors in the various aspects presented throughout this disclosure, the memory may be internal to the processors (e.g., cache or register).

Computer-readable media may be embodied in a computer-program product. By way of example, a computer-program product may include a computer-readable medium in packaging materials. Those skilled in the art will recognize how best to implement the described functionality presented throughout this disclosure depending on the particular application and the overall design constraints imposed on the overall system.

It is to be understood that the specific order or hierarchy of steps in the methods disclosed is an illustration of exemplary processes. Based upon design preferences, it is understood 65 that the specific order or hierarchy of steps in the methods may be rearranged. The accompanying method claims 12

present elements of the various steps in a sample order, and are not meant to be limited to the specific order or hierarchy presented unless specifically recited therein.

The previous description is provided to enable any person skilled in the art to practice the various aspects described herein. Various modifications to these aspects will be readily apparent to those skilled in the art, and the generic principles defined herein may be applied to other aspects. Thus, the claims are not intended to be limited to the aspects shown herein, but is to be accorded the full scope consistent with the language of the claims, wherein reference to an element in the singular is not intended to mean "one and only one" unless specifically so stated, but rather "one or more." Unless specifically stated otherwise, the term "some" refers to one or more. A phrase referring to "at least one of" a list of items refers to any combination of those items, including single members. As an example, "at least one of: a, b, or c" is intended to cover: a; b; c; a and b; a and c; b and c; and a, b and c. All structural and functional equivalents to the elements of the various aspects described throughout this disclosure that are known or later come to be known to those of ordinary skill in the art are expressly incorporated herein by reference and are intended to be encompassed by the claims. Moreover, nothing disclosed herein is intended to be dedicated to the public regardless of whether such disclosure is explicitly recited in the claims. No claim element is to be construed under the provisions of 35 U.S.C. §112, sixth paragraph, unless the element is expressly recited using the phrase "means for" or, in the case of a method claim, the element is recited using the phrase "step for."

What is claimed is:

- 1. A method of wireless communication, comprising:
- determining whether timing of a non-serving radio access technology (RAT) is known;
- estimating when an identity of a base station in the nonserving RAT will be transmitted;
- clearing enough consecutive time slots corresponding to the estimate, by canceling at least one channel in at least one of the consecutive time slots, to measure a timing of the non-serving RAT and to verify the identity of the base station in the non-serving RAT when it is time to report on the non-serving RAT base station and the timing is unknown;
- acquiring timing and verifying the identity of the base station during the cleared time slots; and
- resuming communications on the cleared time slots after the identity is verified.
- 2. A method of wireless communication, comprising:
- determining whether timing of a non-serving radio access technology (RAT) is known;
- estimating when an identity of a base station in the nonserving RAT will be transmitted;
- clearing enough consecutive time slots corresponding to the estimate, by canceling at least one channel in at least one of the consecutive time slots, to verify the identity of the base station in the non-serving RAT when it is time to report on the non-serving RAT base station and the timing is known;
- verifying the identity of the base station during the cleared time slots; and
- resuming communications on the cleared time slots after the identity is verified.
- 3. An apparatus for wireless communication, comprising: means for determining whether timing of a non-serving radio access technology (RAT) is known;
- means for estimating when an identity of a base station in the non-serving RAT will be transmitted;

means for clearing enough consecutive time slots corresponding to the estimate, by canceling at least one channel in at least one of the consecutive time slots, to measure a timing of the non-serving RAT and to verify the identity of the base station in the non-serving RAT when it is time to report on the non-serving RAT base station and the timing is unknown; and

means for acquiring timing and verifying the identity of the base station during the cleared time slots; and

means for resuming communications on the cleared time 10 slots after the identity is verified.

4. An apparatus for wireless communication, comprising: means for determining whether timing of a non-serving radio access technology (RAT) is known;

means for estimating when an identity of a base station in 15 the non-serving RAT will be transmitted;

means for clearing enough consecutive time slots corresponding to the estimate, by canceling at least one channel in at least one of the consecutive time slots, to verify the identity of the base station in the non-serving RAT when it is time to report on the non-serving RAT base station and the timing is known; and

means for verifying the identity of the base station during the cleared time slots; and

means for resuming communications on the cleared time 25 slots after the identity is verified.

5. A non-transitory computer-readable medium having non-transitory program code for wireless communication in a wireless network recorded thereon, the program code being executed by a processor and comprising:

program code to determine whether timing of a non-serving radio access technology (RAT) is known;

program code to estimate when an identity of a base station in the non-serving RAT will be transmitted;

program code to clear enough consecutive time slots corresponding to the estimate, by canceling at least one channel in at least one of the consecutive time slots, to measure a timing of the non-serving RAT and to verify the identity of the base station in the non-serving RAT when it is time to report on the non-serving RAT base 40 station and the timing is unknown;

program code to acquire timing and verify the identity of the base station during the cleared time slots; and

program code to resume communications on the cleared time slots after the identity is verified.

6. A non-transitory computer-readable medium having non-transitory program code for wireless communication in a wireless network recorded thereon, the program code being executed by a processor and comprising:

program code to determine whether timing of a non-serv- 50 ing radio access technology (RAT) is known;

14

program code to estimate when an identity of a base station in the non-serving RAT will be transmitted;

program code to clear enough consecutive time slots corresponding to the estimate, by canceling at least one channel in at least one of the consecutive time slots, to verify the identity of the base station in the non-serving RAT when it is time to report on the non-serving RAT base station and the timing is known;

program code to verify the identity of the base station during the cleared time slots; and

program code to resume communications on the cleared time slots after the identity is verified.

7. An apparatus for wireless communication, comprising: a memory; and

at least one processor coupled to the memory, the at least one processor being configured:

to determine whether timing of a non-serving radio access technology (RAT) is known;

to estimate when an identity of a base station in the non-serving RAT will be transmitted;

to clear enough consecutive time slots corresponding to the estimate, by canceling at least one channel in at least one of the consecutive time slots, to measure a timing of the non-serving RAT and to verify the identity of the base station in the non-serving RAT when it is time to report on the non-serving RAT base station and the timing is unknown;

to acquire timing and verify the identity of the base station during the cleared time slots; and

to resume communications on the cleared time slots after the identity is verified.

8. An apparatus for wireless communication, comprising: a memory; and

at least one processor coupled to the memory, the at least one processor being configured:

to determine whether timing of a non-serving radio access technology (RAT) is known;

to estimate when an identity of a base station in the non-serving RAT will be transmitted;

to clear enough consecutive time slots corresponding to the estimate, by canceling at least one channel in at least one of the consecutive time slots, to verify the identity of the base station in the non-serving RAT when it is time to report on the non-serving RAT base station and the timing is known;

to verify the identity of the base station during the cleared time slots and

to resume communications on the cleared time slots after the identity is verified.
